Differences between Windows XP and Windows 7 when compiling font modules

In Windows 7, BR font module names with 8 characters are generated differently than in Windows XP. This leads to varying compiler results and therefore problems transferring existing transfer lists.

Cause	In Windows 7, the file names of fonts that have more than 8 characters are generated differently than in Windows XP.
Reaction	With Automation Studio 3.0.90 and higher, font modules are given consistent names. The name consists of the first 5 characters of the file name + 3 letters from the hash value (MD5) for the name. This only applies to fonts whose names are more than 8 characters long (e.g. ARIALUNIBR. TTF)
Remedy	Transfer lists that still contain the old names must be remade.
